

7 Cognition And Intelligence

7.1 Class Notes

-

7.2 Study Guide Material

- Elaboration is a process by which a stimulus is linked to other information at the time of encoding.
- Visual imagery involves the creation of visual images to represent the words to be remembered, and concrete words are much easier to create images of
- Dual-coding theory holds that memory is enhanced by forming semantic or visual codes, since either can lead to recall.
- Self-referent encoding involves deciding how or whether information is personally relevant, that is, information that is personally meaningful is more memorable.
- Structural encoding is shallow processing that emphasizes the physical structure of the stimulus, as in encoding the shapes that form letters in the alphabet.
- Sensory memory is one of two temporary storage buffers that information must pass through before reaching long-term storage. As the name implies, sensory memory preserves information through the senses, in its original form
- flashbulb memories, which are unusually vivid and detailed recollections of momentous events
- Schemas are organized clusters of knowledge about an object or event abstracted from previous experience
- Our poor abilities to retrieve information accurately has been extensively studied and is now known as the misinformation effect,
- Another explanation for why we sometimes fail to retrieve memories accurately is due to source monitoring
- Interference theory, which proposes that people forget information because of competition from other material, is a well-documented process and can account at least for some of our forgetting.
- We repress memories or we are motivated to forget
- Retrograde amnesia results in loss of memories for events that occurred prior to the injury whereas anterograde amnesia results in loss of memories for events that occur after the injury.
- Consolidation refers to a hypothetical process involving gradual conversion of information into durable memory codes for storage in long-term memory. These areas are those around the hippocampus, which comprise the medial temporal lobe.
- Declarative memory handles factual information, whereas nondeclarative memory houses memory for actions, skills, conditioned responses, and emotional memories.
- Episodic memory is an autobiography whereas semantic memory is an encyclopedia.
- Prospective memory involves remembering to perform actions in the future.
- Retrospective memories involve remembering events from the past or previously learned information

7.3 Book Notes
